Head lice infestations: A clinical update

Abstract
Head lice (Pediculus humanus capitis) infestations are not a primary health hazard or a vector for disease, but they are a societal problem with substantial costs. Diagnosis of head lice infestation requires the detection of a living louse. Although pyrethrins and permethrin remain first-line treatments in Canada, isopropyl myristate/ST-cyclomethicone solution and dimeticone can be considered as second-line therapies when there is evidence of treatment failure.

Key Words: Dimeticone solution; Head lice; Infestations; Isopropyl myristate/cyclomethicone solution; Permethrin; Pyrethrin

Head lice (Pediculus humanus capitis) are a persistent and easily communicable cause of infestations, particularly in school-aged children.¹² Unlike body lice, head lice are not a primary health hazard, a sign of poor hygiene or a vector for disease,³⁴ but they are a common societal problem² and relatively expensive to treat. The annual cost of treating head lice in the United States is estimated to be at least US$500 million.⁵

The present practice point updates a previous Canadian Paediatric Society document from 2008⁶ and highlights newer treatment products. It also reviews more recent information concerning treatment failures.

The agent
Head lice are wingless, 2 mm- to 4 mm-long (as adults), six-legged, bloodsucking insects that live on the human scalp.⁷ Infested children usually carry <20 mature head lice (and often <10) at a time, which live three to four weeks if left untreated.³⁹ Head lice live close to the scalp surface, which provides food, warmth, shelter and moisture.³⁹ The head louse feeds every 3 h to 6 h by sucking blood, injecting saliva simultaneously. After mating, the adult female louse can produce five or six eggs (nits) per day for 30 days, each ‘glued’ to a hair shaft near the scalp.⁶ The eggs hatch nine to 10 days later into nymphs that molt several times over the next nine to 15 days to become adult head lice.⁶ The hatched empty eggshells remain on the hair but are not a source of reinfestation. Nymphs and adult head lice can survive for only one to two days away from the human host.⁶ While eggs can survive away from the host for up to three days, they require the higher temperatures found near the scalp to hatch.³

The infestation
An infestation with lice is called pediculosis and usually involves <10 live lice.³ Itching occurs if the individual with lice becomes sensitized to antigenic components in the saliva injected as the louse feeds.²³ On the first infestation, sensitization commonly takes four to six weeks.³⁴ However, some individuals remain asymptomatic and never itch.³ In cases with heavy infestations, secondary bacterial infection of the excoriated scalp may occur.

Transmission
Head lice are spread mainly through direct head-to-head (hair-to-hair) contact.²⁴¹¹ Lice do not hop or fly, but can crawl rapidly (23 cm/min under natural conditions).¹⁰ The role of fomites in transmission is controversial.¹⁰ Two studies from Australia suggest that in the home, pillowcases present only a small risk¹¹ while in the classroom, carpets pose no risk.¹² Pets are not vectors for human head lice.¹³

Diagnosis
Definitive diagnosis of head lice infestation requires the detection of a living louse (Figure 1).²³⁴⁶ The
presence of nits indicates a past infestation that may not be currently active.

Figure 1) An adult louse measures 2 mm in length. Reproduced with permission from the National Pediculosis Association: http://www.headlice.org/faq/lousology.htm.

Because head lice move quickly, their detection requires a degree of expertise and experience. One Israeli study involving experienced parasitologists found that using a fine-toothed lice comb was four times more effective and twice as fast as visually examining the scalp to detect live head lice and diagnose an infestation.

Another study documented that health care providers and lay personnel frequently overdiagnose or misdiagnose pediculosis and often fail to distinguish active from past infestations, particularly when relying on nit detection only. School nurses were adept at spotting nits but less able to distinguish active from past infestations. A viable nit is most likely to be found <0.6 cm away from the scalp. It is seen on microscopy as an intact, hydrated mass or developing embryo. Without microscopy, the ability to distinguish viable from nonviable nits is difficult, which is why diagnosing an infestation by nit detection alone is not reliable.

Finding nits close to the scalp is, at best, a modest predictor of possible active infestation. While one study from Georgia found that having ≥5 nits within 0.6 cm of the scalp was a risk factor for infestation in children, <32% of such cases were actively infested. For children with <5 nits close to the scalp, only 7% became actively infested. Therefore, having nits close to the scalp does not necessarily indicate that a live infestation is underway or will occur.

**Treatment**

Well-established treatment options for a proven head lice infestation include topical insecticides and oral agents. Non-insecticidal products that have been approved by Health Canada since the last CPS statement was published in 2008 can all be obtained over the counter.

**Topical insecticides**

Table 1 lists the topical insecticides (pyrethrins and permethrin 1%) currently available in Canada for treating head lice infestations, with their active ingredients, methods of use and other guidance. Two other products, malathion lotion (0.5%) and crotamiton lotion (10%), are not available in Canada.

**Toxicity:** Both pyrethrins and permethrin have minimal percutaneous absorption and favourable safety profiles. To minimize exposure elsewhere on the body to a topical insecticide, do not sit a child in the bath to rinse hair. Instead, protect the skin with towels and rinse well, using cool water.

Lindane is no longer considered acceptable therapy for head lice because of the potential risks for neurotoxicity and bone marrow suppression following percutaneous absorption. The Food and Drug Administration in the United States has issued periodic advisories concerning the use of lindane-containing products for the treatment of lice and scabies. Neurological side effects have been reported in people who used lindane correctly, although the most serious outcomes, including death and hospitalizations, occurred after multiple applications or oral ingestion. A safe interval for the reaplication of lindane has not been established. The pharmaceutical use of lindane has also been banned in California since 2002 due to concerns about its presence in waste water. A follow-up study published in 2008 showed a marked reduction of lindane levels compared with levels before the California ban. The WHO has recently recategorized lindane as a probable carcinogen.
Resistance: An increasing resistance of head lice to pyrethrins, permethrin and lindane has been reported. In 2010, Marcoux et al.[20] found a resistant allele (R allele) frequency in 133 of 137 head lice populations tested for Canada, which could explain treatment failure rates. However, because these products are effective in more cases than these data imply, the precise relationship between R allele and treatment failure remains unclear. Rule out the following much more common possibilities before considering resistance:[4][15]

- Misdiagnosis or over-diagnosis. A true diagnosis requires detecting live lice before treatment; and

- Reinfestation after a previous treatment.

If two permethrin applications seven days apart do not eradicate live lice, consider administering a full treatment course using a medication from another class.

Note especially that topical insecticides may normally cause scalp rash, itching or a mild burning sensation.[8] Be sure to remind families that itching after treatment with a topical insecticide is NOT a symptom of reinfestation. As with the initial diagnosis, diagnosing a reinfestation requires the detection of live lice. If post-treatment itching is bothersome, a topical steroid and/or an antihistamine may provide relief.[4]

Topical noninsecticidal products
Health Canada has approved the use of a new noninsecticidal product containing isopropyl myristate 50% and ST-cyclomethicone 50% (Resultz, Nycomed-Takeda Canada Inc.) for the treatment of head lice in children ≥4 years of age. This product works by dissolving the insect’s waxy exoskeleton, causing dehydration and death. The product is applied to a dry scalp and rinsed off in 10 minutes. Because this product is not ovicidal, a second application one week later is recommended. Several small phase-II trials (200 to 300 participants only) have demonstrated efficacy and minimal side effects, the most common being mild erythema and pruritus of the scalp.[21]-[24]

A noninsecticidal product containing 92% concentration of silicone oil dimeticone (NYDA) is also available in Canada.[25][26] Silicone oil dimeticone affects the insect’s breathing apparatus and is effective against lice, nymphs and egg embryos. A second treatment is recommended after 8 to 10 days. This product is not recommended for use in children <2 years of age. To date, neither toxicity nor resistance are reported to be at issue.

Benzyl alcohol lotion 5% (Ulesfia lotion) is also approved for use in Canada. Benzyl alcohol is highly effective against live lice but is not ovicidal. A second treatment nine days after the first treatment is required for a full treatment course. Benzyl alcohol lotion is approved for use in individuals six months to 60 years of age, and skin irritation is the only common side effect.[27] This product is quite expensive compared with most other head lice treatments.

Oral head lice therapies
Data to support the use of oral agents in treating head lice are limited. Although trimethoprim-sulfamethoxazole was used to treat head lice in one randomized trial,[28] both alone and in combination with topical permethrin, concerns have since been raised about the diagnostic criteria used and this drug’s potential for promoting bacterial resistance and reducing its value in other settings if use against head lice becomes widespread.[29] There are no published large trials for trimethoprim-sulfamethoxazole, and it is not approved for use in Canada against head lice.

There have been reports[31] regarding both the oral and topical use of ivermectin, an antihelminthic agent, to treat head lice. Treatment consists of two single oral doses of 200 µg/kg spaced seven to 10 days apart. Ivermectin is potentially neurotoxic and should not be used in children who weigh <15 kg.[8] This drug is available in Canada only through Health Canada’s Special Access Programme.[31] While topical ivermectin 0.5% is now available in the United States, it is not yet approved in Canada. A study of concentrations from 0.15% to 0.5% found best results of being louse-free with 0.5%.[32] A second study of 0.5% topical ivermectin found 94.9% of treated individuals to be louse-free after two days. Occasional cases of minor eye irritation and mild skin burning were the only reported side effects.[33]

Wet combing
There is little evidence to support wet combing as a primary treatment for head lice.[21][34] In a randomized trial of 4037 school-children in Wales, United Kingdom[21] the mechanical removal of lice by combing wet hair with a fine-toothed comb every three to four days for two weeks was compared with two applications of topical 0.5% malathion lotion, seven days apart.[21] Wet combing resulted in a cure (no detection of live lice after two weeks) in 38% of cases, while the malathion treatment cured 78% of cases.[21] Another study combining wet combing with topical 1% permethrin treatment did not improve on results obtained with permethrin treatment alone when assessed at day two, eight,
nine and 15 (combing 72.7%, no combing 78.3%).\(^{[21]}\)
While vinegar has been suggested as a home remedy to aid wet combing, there are no studies showing its benefit.

**Other products**
A number of household products, such as mayonnaise, petroleum jelly, olive oil, tub margarine and thick hair gel, have been suggested as treatments for head lice. Applying a thick coating of such agents to the hair and scalp and leaving it on overnight theoretically occludes lice spiracles and decreases respiration.\(^{[8]}\) However, these products are not very effective at killing of lice compared with topical insecticides.\(^{[3]}\) There are no published trials on the safety or efficacy of such home remedies.

While natural products (eg, tea tree oil) and aromatherapy have been used to treat head lice, efficacy and toxicity data are not available to support either therapy.\(^{[3][9]}\) One small study in Israel\(^{[34]}\) found that a product containing coconut, anise and ylang ylang oils, applied to hair three times at five-day intervals, was as successful as the control pediculicide.

Using flammable, toxic and dangerous substances like gasoline or kerosene to treat head lice or using products intended for treating lice in animals are not recommended under any circumstances.

*An itchy or burning sensation on the scalp after treatment does not indicate reinfection and need for retreatment. Using a topical steroid or antihistamine may help.

<tr>
<th><strong>School and child care head lice and nit policies</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>There is no sound medical rationale for excluding a child with nits or live lice from school or child care. A full course of treatment and avoiding close head-to-head activities are recommended. The American Academy of Pediatrics and the Public Health Medicine Environmental Group in the United Kingdom also discourage ‘no nit’ school policies.[2][4][10]</td>
</tr>
</tbody>
</table>

The families of children in the same classroom or child care group where a case of active head lice has been detected should be alerted. Information on diagnosis and management of head lice from a credible source should be shared, along with clear messages that head lice are neither a disease risk nor a sign of lack of cleanliness.

<table>
<thead>
<tr>
<th><strong>The role of environmental decontamination</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Data on whether disinfecting personal, school or household items decreases the likelihood of reinfection are lacking.[11][12] Because lice live close to the scalp, nits are unlikely to hatch at room temperature[3][10] and environmental cleaning is not warranted. At most, washing items in close or prolonged contact with the head (eg, hats, pillowcases, brushes and combs) may be warranted. Wash such items in hot water (≥66°C) and dry them in a hot dryer for 15 minutes. Storing any item in a sealed plastic bag for two weeks will kill both live lice and nits.[3][11]</td>

<tr>
<th><strong>The role of health care providers</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Given the prevalence of head lice infestations and the anxiety they cause — for children, parents and child care or school staff — health care providers are uniquely qualified to dispel myths and provide accurate information on diagnosis, misdiagnosis and management strategies.[2] Be sure to reinforce with parents and local school authorities that while head lice infestations are common, they do not indicate uncleanliness or spread disease.</td>
</tr>
</tbody>
</table>

**Recommendations**

Clinicians should provide parents with the most up-to-date information on head lice, helping to dispel long-held myths. Key messages include:

- Head lice infestations are common in school-children but are not associated with disease spread or poor hygiene.
- Head lice infestations can be asymptomatic for weeks.
- Misdiagnosis of head lice infestations is common. Diagnosis requires detection of live head lice. Detecting nits alone does not indicate active infestation.
- Environmental cleaning or disinfection following the detection of a head lice case is not warranted. Head lice or nits do not survive for long away from the scalp.

Clinicians should provide the following advice about treatment of head lice:

- Treatment with an approved, properly applied, topical head lice insecticide (two applications seven to 10 days apart) is recommended when a case of active infestation is detected.

- When there is evidence of treatment failure – detection of live lice – using a full course of topical treatment from a different class of medication is recommended.

- The scalp may be itchy after applying a topical insecticide but itching does not indicate treatment resistance or a reinfestation.

- Topical insecticides can be toxic. Take care to avoid unnecessary exposure and, when indicated, minimize skin contact beyond the scalp.

- Excluding children with nits or live lice from school or child care has no rational medical basis and is not recommended.

- For children ≥2 months of age, permethrin and pyrethrins are acceptable treatments for confirmed cases of head lice. Dimethicone can be used in children ≥2 years of age. Myristate/ST-cyclomethicone can be used in children ≥4 years of age. Benzoyl alcohol lotion is comparatively expensive but can be used in children ≥6 months of age.

Schools and child care facilities should consider that:

- Excluding children with nits or live lice from school or child care has no rational medical basis and is not recommended.
